(54) **ALUMINUM PIGMENT**

(57) An aluminium pigment, wherein the mean particle diameter  $d_{50}$  is 5 - 35  $\mu\text{m}$ , the ratio of mean particle diameter  $d_{50}$  ( $\mu\text{m}$ ) to mean thickness  $t$  ( $\mu\text{m}$ ) is 30 - 90, and the mean surface roughness  $R_a$  is 20 nm or less.

**FIG.1**

EP 1 080 810 A1

## Description

## TECHNICAL FIELD

5 [0001] The present invention relates to an aluminium pigment used in a high quality metallic paint field including high quality metallic paints for automobile bodies and parts, metallic paints for automobile repairing, household metallic paints, industrial metallic paints and the like, high quality metallic printing ink field including gravure printing, offset printing, screen printing and the like, and high quality metallic resin additive field, and manufacturing process thereof.

10 [0002] More specifically, the present invention relates to an aluminium pigment having high brightness and high flip-flop effect, which can provide a high light reflectance never seen before and an extremely high flip-flop effect, that is, an optical anisotropy, to paint films, prints or films formed by conventional methods in the above described applications, and manufacturing process thereof.

## BACKGROUND ART

15 [0003] Aluminium pigments have been popularly used in the above described fields as a pigment having both a peculiar metallic texture which can not be seen with any other pigment and an excellent hiding power.

[0004] In recent years, a fashionable characteristic of automobile body painting has become more and more important, and it has been evaluated with the same or higher sense of value than are the intrinsic functions of automobiles. Especially in a trend of the fashion in automobile body painting in recent years, white color or simple glittering silver metallic tone which was deep-seated before, has lost its popularity, and a demand for a paint film having a strong brightness and a strong optical anisotropy, by which appearance of the painting changes depending on a viewing angle, has arisen.

20 [0005] As for the aluminium pigments aiming at obtaining such a high reflectance, and the manufacturing processes thereof, the following is known.

[0006] Japanese Patent No. 2575516 describes an aluminium pigment having both a high hiding power and a high light reflectance. JP-A-49-14358 also describes a process to obtain an aluminium pigment having a high reflectance by polishing surfaces of aluminium powder by means of wet ball-mill method. In addition, JP-B-54-36607 describes a process to form a metallic paint film which is excellent in a sparkling effect. Furthermore, JP-A-8-170034 describes an aluminium pigment providing a paint film having strongly brightening texture and excellent appearance. Still further, JP-A-7-509266 discloses metal-powder-pigment particles which are ground almost spherically.

30 [0007] However, none of the art can satisfy high brightness and high flip-flop effect which are presently required for an aluminium pigment.

## DISCLOSURE OF THE INVENTION

35 [0008] The present invention provides an aluminium pigment having a high grade of optical characteristics, particularly, a high brightness and a high flip-flop effect, and a manufacturing process which enables manufacturing of such an aluminium pigment very easily with good reproducibility.

40 [0009] In order to solve the above problems, the inventors studied relationships between basic physical properties or optical characteristics of the aluminium pigment and manufacturing conditions earnestly and fundamentally and, as a result, found that the optical characteristics such as high brightness and high flip-flop effect can be revealed by controlling a mean particle diameter, a ratio of the mean particle diameter to the mean thickness and mean surface roughness of an aluminium pigment within respective specified ranges. Thus, the present invention was completed.

45 [0010] The present invention provides an aluminium pigment, which has the mean particle diameter  $d_{50}$  of 5 - 35  $\mu\text{m}$ , the ratio of the mean particle diameter  $d_{50}$  ( $\mu\text{m}$ ) to the mean thickness  $t$  ( $\mu\text{m}$ ) of 30 - 90, and the mean surface roughness  $R_a$  of 20 nm or less. The present invention also provides the above described aluminium pigment which further has a mean height of irregularity in the surface roughness curve  $R_c$  of 80 nm or less.

50 [0011] In addition, the present invention further provides process for manufacturing the above described aluminium pigment, comprising grinding aluminium by means of a medium mixing mill or ball mill using grinding balls with a specific gravity of 5 or less in a weight ratio of 2 - 100 to aluminium in a grinding solvent(s). Still further, the present invention provides the above described manufacturing process wherein the diameter of the grinding balls is 4 mm or less in the above manufacturing process.

## BRIEF DESCRIPTION OF THE DRAWINGS

## [0012]

5 Figure 1 shows the photographs by an atomic force microscope (AFM) depicting the surface morphology of the aluminium-pigment particles according to the invention (Example 1).

Figure 2 shows the photographs by an atomic force microscope (AFM) depicting the surface morphology of the aluminium-pigment particles according to Comparative Example 1.

## 10 BEST MODE FOR CARRYING OUT THE INVENTION

[0013] In the present invention, mean particle diameter  $d_{50}$  ( $\mu\text{m}$ ), mean thickness  $t$  ( $\mu\text{m}$ ), water covering area WCA ( $\text{m}^2/\text{g}$ ), mean surface roughness  $R_a$  (nm) and mean height  $R_c$  (nm) of an aluminium pigment are defined as follows, respectively.

15 [0014] The mean particle diameter  $d_{50}$  ( $\mu\text{m}$ ) can be measured using Laser Micron Sizer LMS-24 (made by SEISHIN KIGYO Co., Ltd.), and is in a range of 5 - 35  $\mu\text{m}$ . The mean particle diameter  $d_{50}$  may be selected within the range of extremely fine mesh, fine mesh, medium mesh, coarse mesh or extremely coarse mesh depending on the design required. The particles with the mean particle diameter of 5  $\mu\text{m}$  or larger tend to orient themselves along a given direction in a paint film, and are easy to reveal a desirable brightness due to reduced light scattering. And in the parti-  
20 cles with a mean particle diameter of 35  $\mu\text{m}$  or less, little portion of the particles protrudes over the surface of paint film because the particle size does not exceed the thickness of the paint film. As a result, they are good for practical uses because they can give a metallic paint film with a fine texture.

[0015] The mean thickness  $t$  ( $\mu\text{m}$ ) is a value calculated, according to the following equation, from WCA ( $\text{m}^2/\text{g}$ ), water covering area per 1 g of metal component, which is obtained by measurement.

25

$$t = 0.4 / \text{WCA}$$

[0016] The above described calculation method for the mean thickness is described in, for example, J. D. Edwards & R. I. Wray, *Aluminium Paint and Powder*, 3rd Ed., Reinhold Publishing Corp. New York (1995), Page 16 - 22.

30 [0017] Water covering area is measured according to the procedure of JIS K 5906-1991 after applying a determined pretreatment. It should be noted that the aluminium pigment of the present invention is of a non-leaving type though JIS describes a measuring method of the water covering area for the case of leaving type. However, the measuring method of water covering area in the present invention is totally same as the one for the case of leaving type described in JIS K 5906-1991 except for applying a pretreatment with 5% stearic acid in a mineral-spirits solution to the  
35 sample. The procedure for the pretreatment of the sample is described in *Review on the Raw Materials for Paints*, No. 156, Page 2 - 16 (Edited by Asahi Chemical Industry Co., Ltd. on September 1st, 1980).

[0018] The ratio of the mean particle diameter  $d_{50}$  to the mean thickness  $t$  in the present invention is given by  $d_{50}/t$ , and means so called "flatness" of an aluminium pigment (the ratio being referred to as "flatness" hereinafter in some cases). As the aluminium powder is ground by means of a medium mixing mill or ball mill, the aluminium particles  
40 increase gradually in flatness and become easily folded when they are flattened over a certain degree. Generally, flatness over 200 makes a particle easily cracked and folded. For an aluminium pigment of the present invention, flatness is 30-90. Flatness of 90 or lower gives a smooth surface to an aluminium pigment, and results in improved brightness and also a high flip-flop effect by reducing light scattering at the surface and increasing a regular reflectance. And the flatness of 30 or higher enables a paint film to maintain a sufficient hiding power which is an important function of alu-  
45 minium pigments, and makes the pigments practically usable.

[0019] The mean surface roughness  $R_a$  in the present invention is calculated according to the following method.

[0020] As an observation method for a surface morphology of an aluminium pigment, an atomic force microscope (abbreviated as AFM hereinafter) TMX-2010 (made by Topometrix) is used. As a pretreatment, an aluminium pigment as a sample is cleaned up by ultrasonic cleaning with excess methanol and chloroform, vacuum-dried, dispersed again  
50 in acetone, then dropped on a Si wafer, and air-dried. Determination of surface roughness using AFM is carried out by plotting a surface-roughness curve (a line profile of surface irregularity) with 300 scans in 5- $\mu\text{m}$  square of visual field for an aluminium pigment particle which is not overlapped with another aluminium pigment particle, and calculating an arithmetic mean roughness of the roughness curve (arithmetic mean of absolute height values within 5- $\mu\text{m}$  base length). The base length is 5  $\mu\text{m}$  here, though it basically varies depending on the mean particle diameter  $d_{50}$ . In the  
55 present invention, "mean surface roughness  $R_a$  (nm)" is defined as an arithmetic mean value of arithmetic mean roughness values which are obtained for 3 or more visual fields. The terminology relating to the surface roughness are based on JIS B0660:1998.

[0021] The mean surface roughness  $R_a$  of the aluminium pigment of the present invention is 20 nm or lower, pref-

erably 15 nm or lower. When Ra was 20 nm or lower, the pigments showed extremely superior brightness together with good flip-flop effect due to their high regular reflectance of light at their surfaces.

**[0022]** The mean height Rc of irregularity in the surface-roughness curve of an aluminium pigment is expressed with a sum of the mean value of absolute values of mountaintop heights and the mean value of absolute values of ravine depths in a surface roughness curve obtained as described above. More concretely, Rc in the present invention is an arithmetic mean value of the arithmetic mean heights of surface-roughness curves which are obtained by measuring 3 or more visual fields.

**[0023]** The mean height Rc of an aluminium pigment of the present invention is preferably 80 nm or lower. When the mean height Rc was 80 nm or lower, the pigments showed extremely superior high brightness together with good flip-flop effect.

**[0024]** The aluminium pigment of the present invention has little irregularities on the surface and few extremely fine particles adhered on the surface. It contains a fairly large proportion of the aluminium pigment particles each of which has an uniform thickness through all areas from the center to the edge, in an observation with a scanning electronic microscope (SEM).

**[0025]** As for the manufacturing process of an aluminium pigment of the present invention, preferably it is manufactured by grinding atomized aluminium powder as a raw material especially by means of a medium mixing mill or ball mill.

**[0026]** The specific gravity of grinding balls used in the ball mill or the like is preferably 5 or less. The specific gravity of 5 or less enables to obtain an aluminium pigment having little surface roughness. More preferably, the specific gravity is 4 or below. It should be noted that specific gravity of the grinding ball should be desirably higher than the specific gravity of a grinding solvent. If specific gravity of the grinding ball is lower than that of the grinding solvent, grinding is not performed because the grinding balls are floated up in the solvent and no shear stress among the grinding balls is produced.

**[0027]** As a material for such grinding balls, any material is acceptable without any special limitation so long as it satisfies the above specific gravity range. For example, glass balls, alumina balls, zirconia balls or the like can be used. Desirably, glass balls are used from the view points of economy and quality. The surface roughness of grinding balls is preferably 0.08  $\mu\text{m}$  (Grade G40) or less in the surface roughness Ra (maximum) defined in JIS B 1501 for a steel ball for ball bearing. More preferably, it is 0.04  $\mu\text{m}$  (Grade G20) or less.

**[0028]** The diameter of grinding balls is suitably 1 - 4 mm. Diameter of 4 mm or less is suitable because it can suppress the remarkable prolongation of grinding time and also heightens homogeneity of mill contents during grinding. The diameter of 1 mm or more is also suitable because it can prevent an occurrence of the so-called group motion, i.e., the phenomenon in which grinding balls do not move independently but move as a group or a mass resulting in decrease of shear stress among the grinding balls and failure of grinding.

**[0029]** As for the aluminium powder as a raw material, atomized aluminium powder which contains little amount of impurity other than aluminium is desirable. The purity of the atomized aluminium powder is preferably 99.5% or more, more preferably 99.7% or more, and most preferably 99.8% or more.

**[0030]** The mean particle diameter of atomized aluminium powder is suitably 2 - 20  $\mu\text{m}$ , and more suitably 3 - 12  $\mu\text{m}$ . An aluminium pigment with a diameter of 2  $\mu\text{m}$  or larger can maintain its surface conditions and particle shape well. In addition, an aluminium pigment with a diameter of 20  $\mu\text{m}$  or smaller is suitable because it can keep a flattening time of the aluminium-pigment surface by grinding short, and the history of receiving shear stress from grinding balls less, and prevent the surface from having significant irregularities which tend to increase with the flattening time.

**[0031]** Preferably, the shape of atomized aluminium powder is spherical, teardrop-like and the like. A needle-like powder or that with an indeterminable shape is not preferable because the shape of aluminium pigment tends to collapse easily during grinding.

**[0032]** The type of grinding solvent is not specially limited, and solvents having low viscosities, for example, hydrocarbon-based solvents, such as mineral spirits and solvent naphtha which have been used, alcohol-based, ether-based, ketone-based, ester-based solvents and the like may be used.

**[0033]** As for grinding conditions for the aluminium powder, the ratio of the weight of grinding balls to the weight of aluminium in the aluminium powder is preferably 2 - 100, more preferably 10 - 100, and most preferably 14 - 65. The ratio of the weight of grinding balls to the weight of aluminium in the aluminium powder of 2 or more is desirable because it gives an aluminium pigment small surface roughness, high brightness and flip-flop effect. If the above described ratio is 100 or less, both the grinding time and productivity can be kept within practical ranges.

**[0034]** Also, the ratio of the weight of grinding solvent to the weight of aluminium in the aluminium powder is preferably 1.8 - 30, and more preferably 2.6 - 18. Grinding under the condition where the ratio of the weight of grinding solvent to the weight of aluminium exceeds the above described range is not desirable because the reflectance of the aluminium pigment drastically decreases though the hiding power can be increased. This is presumed to be caused by an uneven state in the mill.

**[0035]** In addition, grinding aids may be used. A material for the grinding aids is not specially specified so long as it exhibits characteristics as a non-leaving pigment. Typically, oleic acid, stearyl amine or the like is used. It is used in an

amount of 1 - 50% by weight based on the aluminium powder.

**[0036]** Together with the aluminium pigment of the present invention, mica, color pigment or the like can be jointly used.

**[0037]** Hereunder, representative examples of the present invention are shown. Measuring methods for various physical properties used in the examples and comparative examples are as follows.

① Mean particle diameter:  $d_{50}$

**[0038]** Measurement was carried out using Laser Micron Sizer LMS-24. As a measuring solvent, mineral spirits was used. An ultrasonic dispersion was applied to the samples of aluminium pigment for 2 minutes as a pretreatment.

② Mean thickness:  $t$

**[0039]** Firstly, 1 g of the aluminium pigment was pre-dispersed by adding 1 - 2 ml of 5% stearic acid solution in mineral spirits, followed by adding 50 ml of petroleum benzine, and mixing. After heating at 40 - 45°C for 2 hours, the pigment was filtered under a reduced pressure to obtain a powder. Water covering area was measured with these samples. From these measured data, mean thickness:  $t$  was calculated according to the following formula.

$$t (\mu\text{m}) = 0.4 / \text{WCA} (\text{m}^2/\text{g})$$

③ Mean surface roughness:  $R_a$

**[0040]** Using an atomic force microscope (AFM), line profiles (300 scans) of the aluminium pigment were measured for a visual field of 5- $\mu\text{m}$  square; then arithmetic mean surface roughness was calculated from these data. This procedure was repeated for 3 or more visual fields in total, then  $R_a$  was obtained by calculating an arithmetic mean of these values.

④ Mean height of irregularity in surface roughness curve:  $R_c$

**[0041]** From the same line profiles as obtained in the above ③, the mean height of irregularity in the surface-roughness curve was obtained. The same procedures were repeated for 3 or more visual fields in total; then  $R_c$  was obtained by calculating an arithmetic mean of these values.

⑤ Evaluation of brightness and flip-flop effect

(1) Preparation of paints and paint films

**[0042]** After 5 g of the aluminium pigment were premixed with 8 g of ACRIC No. 2000GL thinner (made by Kansai Paint Co., Ltd.), 97 g of ACRIC No. 2026GL Clear (made by Kansai Paint Co., Ltd.) were further added; then the mixture was shaken for 10 minutes with a paint shaker. From the silver-metallic paint obtained, a paint film was prepared on a sheet of art paper with 9-mil applicator, then dried at room temperature.

(2) Colorimetry

**[0043]** According to the method described in *Research of Paints*, No. 117, Page 67 - 72 (Published by Kansai Paint Co., Ltd. in 1989), an evaluation was carried out using a laser type metallic-texture measuring apparatus ALCOPE LMR-2000 (made by Kansai Paint Co., Ltd.). The measurement was performed under the optical conditions in which a laser light source was arranged at 45 degrees of incident angle, and the receptors were arranged at 0 degree and -35 degrees of light reception angles.

**[0044]** An IV value was obtained at -35 degrees of light-reception angle where the highest light intensity was obtained among reflected laser light, except for the light in a mirror reflection region which was a reflected light from a paint film surface. The IV value is a parameter proportional to an intensity of regular reflection from aluminium pigments, and exhibits an extent of brightness.

**[0045]** Also, a variation in intensity of reflection light was measured by changing an observation angle (light-reception angle). An FF value was obtained by non-dimensionalizing an extent of the variation in intensity of reflection light with a mean reflection intensity. The FF value is a parameter proportional to an extent of orientation of aluminium pigments, and exhibits an extent of pigment flip-flop effect.

## Example 1

[0046] A mixture of 250 g of atomized aluminium powder (mean particle diameter 6  $\mu\text{m}$ ), 1.2 kg of mineral spirits and 25 g of oleic acid, was charged in a ball mill which was 30 cm in inner diameter and 35 cm in length, and then ground at 60 rpm for 10 hours using 15 kg of glass beads (specific gravity 2.6) with a diameter of 3 mm.

[0047] After the grinding was finished, the slurry in the mill was washed out with mineral spirits followed by screening with a vibrating screen of 400 mesh. The slurry under the screen was filtered with a filter, concentrated, and gave a cake of heating residue 80%. The cake obtained was transferred into a vertical mixer, added with a determined amount of solvent naphtha, mixed for 15 minutes, and gave an aluminium pigment of heating residue 75%.

[0048] On the aluminium pigment obtained, evaluations of brightness and flip-flop effect were carried out. Results are shown in Table 1.

## Example 2

[0049] The same procedures as in Example 1 were repeated except that the mean particle diameter of the atomized aluminium powder as a raw material and the grinding time were changed to 10  $\mu\text{m}$  and 15 hours, respectively, and an aluminium pigment was obtained. Evaluations of brightness and flip-flop effect were carried out on this pigment. Results are shown in Table 1.

## Example 3

[0050] The same procedures as in Example 1 were repeated except that the mean particle diameter of the atomized aluminium powder as a raw material, was 8  $\mu\text{m}$ , and the grinding was carried out at 60 rpm for 12 hours using glass beads with a diameter of 2 mm and with the weight ratios of grinding balls and the grinding solvent each to aluminium as shown in Table 1, and an aluminium pigment was obtained. On this pigment, evaluations of brightness and flip-flop effect were carried out. Results are shown in Table 1.

## Comparative Example 1

[0051] The atomized aluminium powder with a mean particle diameter of 30  $\mu\text{m}$  as a raw material and a media agitating mill equipped with a jacket with a capacity of 4.9 L as an apparatus, were used. In a container of the media agitating mill, 9 kg of glass beads with a diameter of 7 mm - 13 mm, 0.9 kg of mineral spirits and 20 g of stearyl amine, were charged. The agitator was rotated at 27 rpm, and 1.5 minutes later, 600 g of the above described aluminium raw material were gradually charged. After completion of the charge, the agitator was rotated at the same rate for another 5 minutes, then operated at 100 rpm for 5 hours for pulverization. After that, the slurry in the media agitating mill was washed out with mineral spirits, and passed through a vibrating screen of 400 mesh. The slurry under the screen was filtered with a filter, concentrated, and gave a cake of heating residue 78%. The cake obtained was transferred into a vertical mixer, added with a determined amount of solvent naphtha, mixed for 15 minutes, and gave an aluminium pigment of heating residue 75%.

[0052] On the aluminium pigment obtained, evaluations of brightness and flip-flop effect were carried out. Results are shown in Table 1.

## Comparative Example 2

[0053] A mixture of 600 g of the atomized aluminium powder (mean particle diameter 20  $\mu\text{m}$ ), 1.2 kg of mineral spirits and 6 g of stearic acid, was charged in a ball mill of 30 cm in inner diameter and 35 cm in length, then ground at 60 rpm for 5 hours using steel balls (specific gravity 7.8) with a diameter of 4.8 mm.

[0054] After the grinding was finished, the slurry in the mill was washed out with mineral spirits, passed through a vibrating screen of 400 mesh. The slurry under the screen was filtered with a filter, concentrated, and gave a cake of heating residue 87%. The cake obtained was transferred into a vertical mixer, added with a determined amount of solvent naphtha, mixed for 15 minutes, and gave an aluminium pigment of heating residue 75%.

[0055] On the aluminium pigment obtained, evaluations of brightness and flip-flop effect were carried out. Results are shown in Table 1.

## Comparative Example 3

[0056] In a ball mill of 30 cm in inner diameter and 35 cm in length, 250 g of spherical atomized aluminium powder (mean particle diameter 12  $\mu\text{m}$ , an aspect ratio approximately 1.5 : 1 to 1 : 1) and 250 g of oleic acid, were charged,

and then pulverized at 60 rpm for 5 hours using steel balls (specific gravity 7.8) with a diameter of 3.2 mm.

**[0057]** After the pulverization was finished, the content of the mill was washed out with mineral oil, and passed through a vibrating screen. The slurry under the screen was filtered with a filter, concentrated, and gave an aluminium pigment of heating residue 95%. The above described measurements were carried out on the powdery aluminium pigment obtained. In preparation of paints for the evaluations of brightness and flip-flop effect, a silver metallic paint was formulated by adjusting the heating residue (95%) of the above described aluminium pigment to a standard heating residue 75%.

**[0058]** In addition, from an observation by a scanning electron microscope, it was found that the shape of the aluminium pigment obtained was not flaky but close to a spherical atomized-aluminium powder of raw material with a smaller aspect ratio than approximately 2 : 1.

**[0059]** The water covering area could not be measured since the shape was not flaky.

#### INDUSTRIAL APPLICABILITY

**[0060]** An aluminium pigment of the present invention is useful as an aluminium pigment for oil-based and water-based metallic paints for automobiles or the like, and also useful for aluminium pigments for inks and resin additives.

Claims

1. An aluminium pigment, wherein the mean particle diameter  $d_{50}$  is 5 - 35  $\mu\text{m}$ , the ratio of mean particle diameter  $d_{50}$  ( $\mu\text{m}$ ) to mean thickness ( $\mu\text{m}$ ) is 30 - 90, and the mean surface roughness  $R_a$  is 20 nm or less.
2. The aluminium pigment according to Claim 1, wherein the mean surface roughness  $R_a$  is 15 nm or less.
3. The aluminium pigment according to Claim 1, wherein mean height  $R_c$  of irregularity in the surface-roughness curve is 80 nm or less.
4. The aluminium pigment according to Claim 2, wherein the mean height  $R_c$  of irregularity in the surface-roughness curve is 80 nm or less.
5. A process for manufacturing the aluminium pigment according to Claim 1, comprising grinding aluminium in a grinding solvent by means of medium mixing mill or ball mill using a grinding ball having a specific gravity of 5 or less in a weight ratio of 2 - 100 to the aluminium.
6. The process according to Claim 5, wherein the weight ratio is 10 - 100.
7. The manufacturing process according to Claim 5, wherein the diameter of the grinding balls is 1 - 4 mm, inclusively.
8. The manufacturing process according to Claim 6, wherein the diameter of the grinding balls is 1 - 4 mm, inclusively.
9. The manufacturing process according to Claim 5, wherein the aluminium to be ground is an atomized aluminium powder and its mean particle diameter is 2 - 20  $\mu\text{m}$ .
10. The manufacturing process according to Claim 5, wherein the grinding solvent is used in a weight ratio of 1.8 - 30 to the weight of aluminium.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/JP99/02072

<b>A. CLASSIFICATION OF SUBJECT MATTER</b> Int.Cl. <sup>6</sup> B22F1/00, C09C1/64, C09C3/04		
According to International Patent Classification (IPC) or to both national classification and IPC		
<b>B. FIELDS SEARCHED</b> Minimum documentation searched (classification system followed by classification symbols) Int.Cl. <sup>6</sup> B22F1/00, C09C1/64, C09C3/04, B22F9/04		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched Jitsuyo Shinan Koho 1926-1996 Toroku Jitsuyo Shinan Koho 1994-1999 Kokai Jitsuyo Shinan Koho 1971-1999 Jitsuyo Shinan Toroku Koho 1996-1999		
Electronic data base consulted during the international search (name of data base and, where practicable, search terms used) JOIS Aruminium Goukin, Aruminiumu Fun, Aruminium, Ganryou, Toryou, Funsai, Masai, Hasai, Boorumiru		
<b>C. DOCUMENTS CONSIDERED TO BE RELEVANT</b>		
Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	JP, 6-68121, B2 (Toyo Alminium K.K.), 31 August, 1994 (31. 08. 94) & EP, 305158, B2	1-10
A	JP, 9-194756, A (Asahi Chemical Industry Co., Ltd.), 29 July, 1997 (29. 07. 97), Page 6, column 10, Par. No. [0030] (Family: none)	1-10
A	JP, 8-41368, A (Hoechst AG.), 13 February, 1996 (13. 02. 96), Page 9, column 15, Par. No. [0073] & EP, 678559, A1	1-10
A	JP, 7-145407, A (Teikoku Piston Ring Co., Ltd.), 6 June, 1995 (06. 06. 95) (Family: none)	1-10
A	Coating Jihou, No. 185, 20 January, 1990 (20. 06. 90), pp. 13-14	1-10
<input type="checkbox"/> Further documents are listed in the continuation of Box C. <input type="checkbox"/> See patent family annex.		
* Special categories of cited documents: "A" document defining the general state of the art which is not considered to be of particular relevance "E" earlier document but published on or after the international filing date "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reasons (as specified) "O" document referring to an oral disclosure, use, exhibition or other means "P" documents published prior to the international filing date but later than the priority date claimed "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art "Z" document member of the same patent family		
Date of the actual completion of the international search 7 July, 1999 (07. 07. 99)		Date of mailing of the international search report 21 July, 1999 (21. 07. 99)
Name and mailing address of the ISA/ Japanese Patent Office		Authorized officer
Facsimile No.		Telephone No.

Form PCT/ISA/210 (second sheet) (July 1992)
